WEEKLY EDITION · JULY 17, 2026

# Weekly Surveillance Review

A seven-day review of zoonotic surveillance signals across 100+ global sources. Week 2026-W29.

This edition summarizes zoonotic, foodborne, and environmental disease signals detected across 100+ global sources over the reporting period. The narrative below highlights the developments most likely to warrant attention, followed by the full data, charts, and source detail.

## ◆ THIS PERIOD'S REPORT

**The dominant story this week is the rapidly escalating Ebola Bundibugyo virus disease outbreak in the Democratic Republic of the Congo, which has now crossed 2,000 confirmed cases across five provinces and recorded more than 750 deaths.** WHO has described it as the fastest-growing Ebola outbreak on record — one official was quoted saying "this is a fire" — and a UN warning this week noted that the economic toll may push close to one million people into poverty. Situation reports 08 and 09 from WHO AFRO, covering data through 12 July, show the outbreak continuing to outpace the public health response, a concern echoed by CDC statements issued on 10 July. The humanitarian picture is further complicated by a threatened full-scale strike among health workers in affected areas over unpaid wages, which, if it materialises, could critically undermine contact tracing and case management. Against this backdrop, Uganda reached a separate milestone — a countdown to declaring the end of its own linked Bundibugyo cases — and a clinical trial evaluating both an Ebola and a Marburg vaccine is now underway in Uganda, a rare piece of encouraging infrastructure news.

Beyond the DRC outbreak, several other signals deserve attention. A Lancet Global Health commentary this week drew on Rwanda's recent Marburg response to offer practical lessons for strengthening Africa's capacity to manage viral haemorrhagic fever outbreaks more broadly — timely given the concurrent pressures on regional health systems. On Nipah virus, a new PLOS NTDs paper and a Lancet Infectious Diseases systematic review both appeared this week, the former arguing for a fundamental reframing of early warning in Bangladesh away from reactive detection and toward anticipatory surveillance. Bangladesh also reported its third human H5N1 avian influenza case of 2026, a quiet but persistent signal that warrants continued monitoring as the country heads into a period of seasonal agricultural activity.

In the Americas, a US cyclosporiasis (an intestinal parasitic infection spread through contaminated food or water) outbreak grew to more than 1,000 cases, prompting a CDC Health Alert Network notice. Mexico is simultaneously reporting a sharp rise in leishmaniasis — cases up roughly 296 percent compared to the same period last year — though the source notes this figure should be interpreted cautiously given possible changes in reporting practice. Oropouche virus continues to circulate in the Colombian Amazon, with new phylogeographic work published this week, and dengue and chikungunya activity in Brazil's Minas Gerais state remains elevated. The Philippines separately recorded hundreds of suspected chikungunya cases in Samar province.

A handful of longer-term surveillance findings also surfaced. Crimean-Congo haemorrhagic fever virus was characterised in central Kazakhstan through integrated tick and animal surveillance, adding detail to its geographic footprint in Central Asia. A new study from Egypt reported the first detection of the emerging zoonotic bacterium *Anaplasma capra* in goats there. And a paper on a 2024 anthrax outbreak in Uganda's Kanungu District — linked to the consumption and handling of livestock carcasses — serves as a reminder that classic zoonotic hazards remain active even as attention focuses on novel threats.

**In the week ahead, the DRC Ebola situation warrants the closest attention**: whether the threatened health worker strike escalates, whether the outbreak expands into additional provinces, and whether international financing commitments keep pace with response needs will be the key indicators to track. The Bangladesh H5N1 case series and the US cyclosporiasis cluster are both worth following for source attribution updates. Progress on the Uganda Ebola/Marburg vaccine trial, if interim safety data emerge, could also be significant for future outbreak response planning across the region.

CHARTS

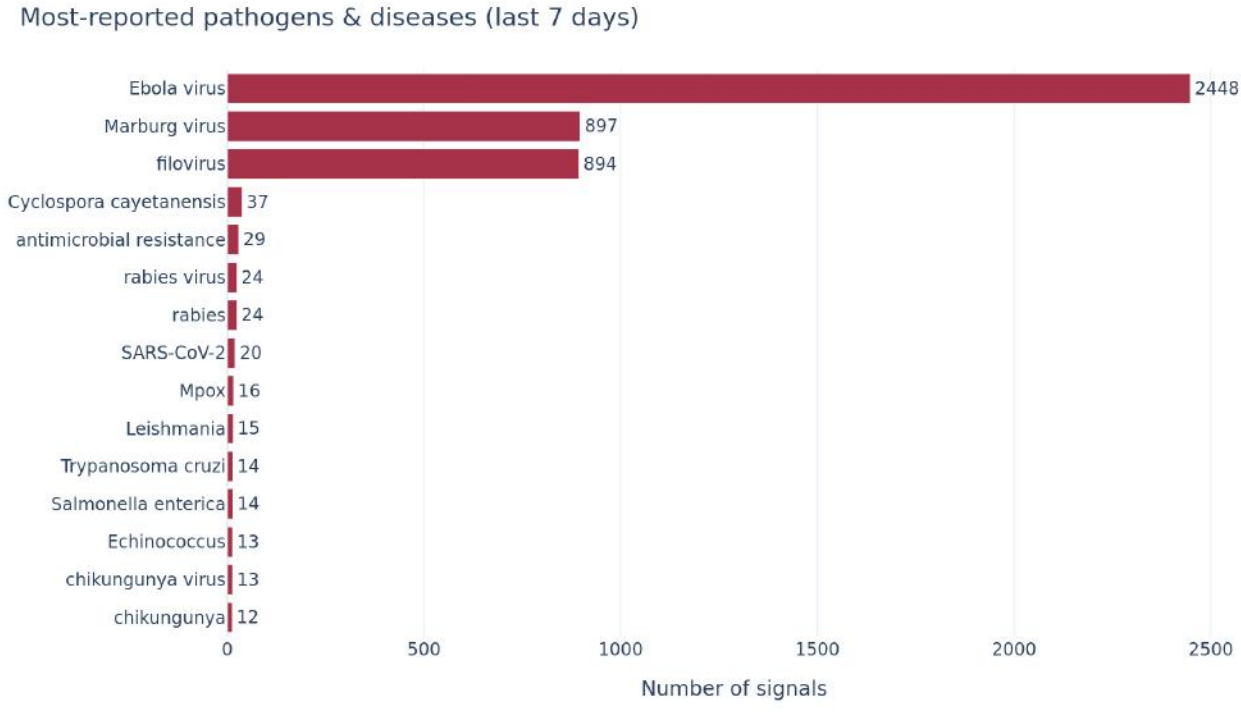

How many signals were detected each day over the last 7 days. Taller bars mean more disease activity was picked up that day.

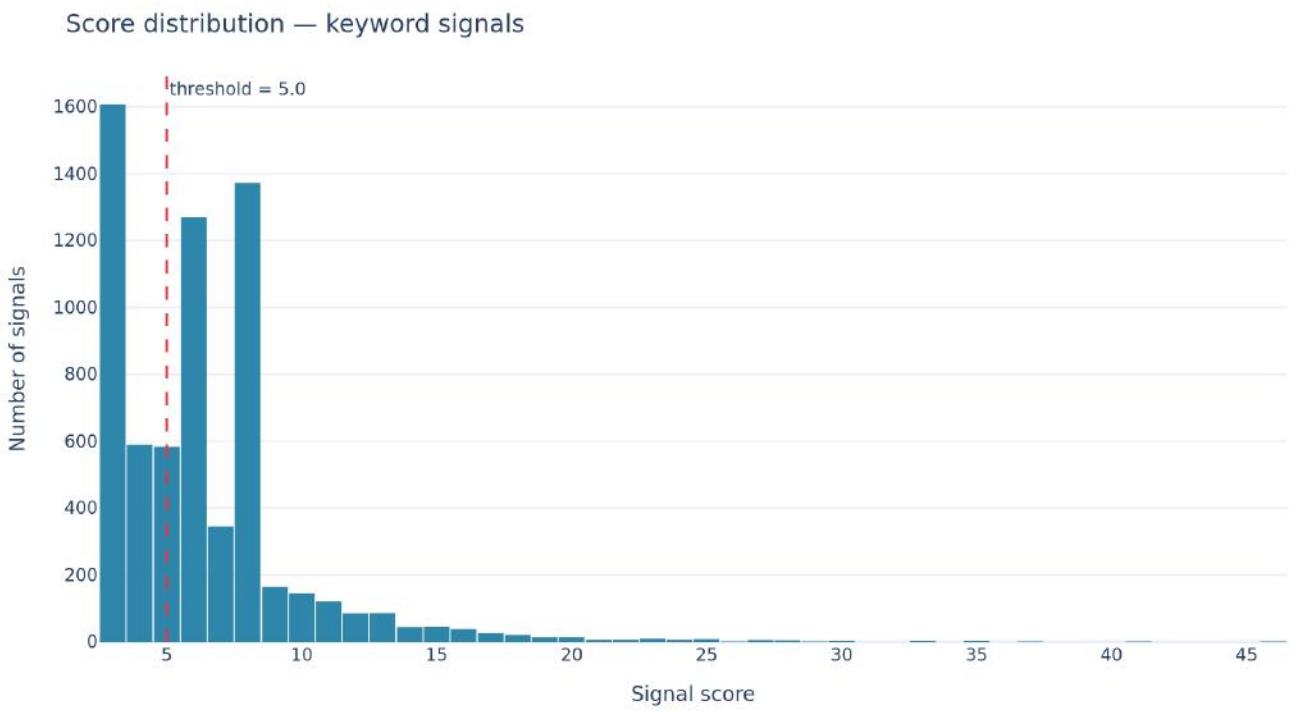

What kinds of things the week's signals were about — outbreak terms, viruses, locations, diseases, bacteria, disease-carriers (vectors), and parasites.

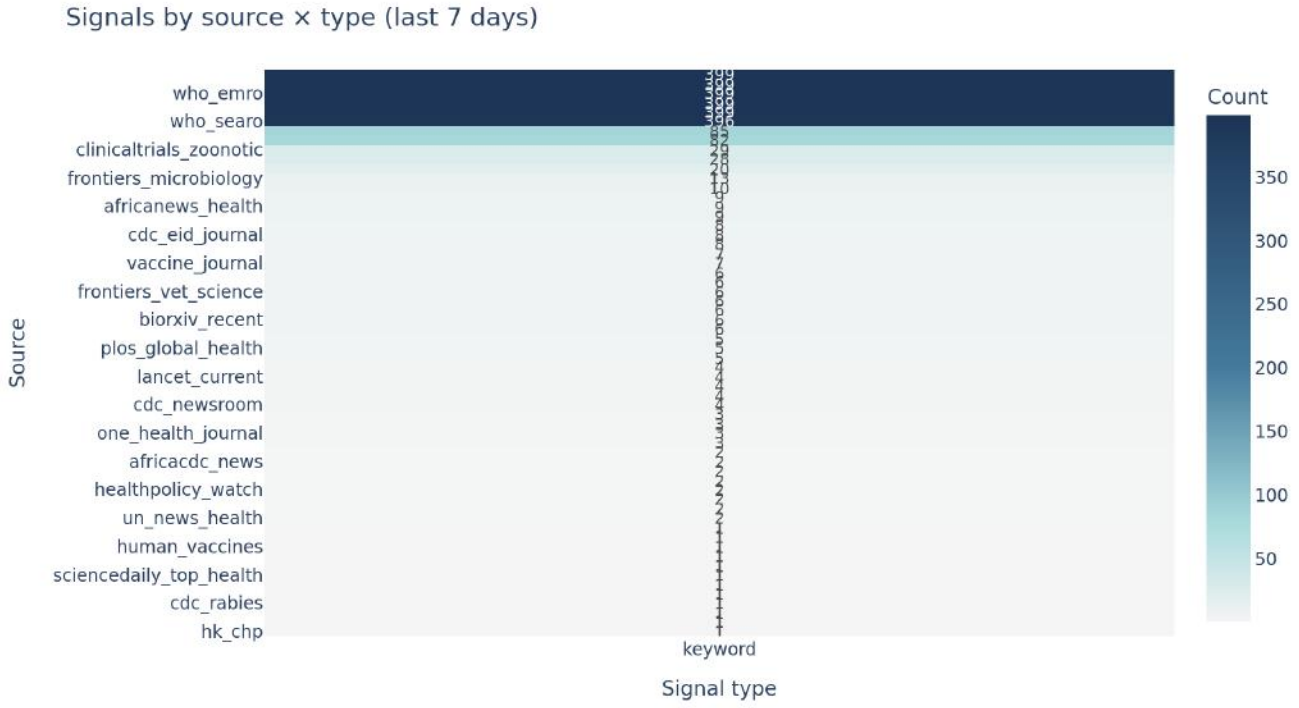

Which countries and regions were named most often in this week's signals.

Which specific pathogens and diseases were reported most often this week.

How signals are spread across priority scores.

Which sources reported the most signals this week.

This brief is compiled automatically from One Health Analytics' global surveillance system. Signal scores are relative indicators of priority, not clinical risk assessments. For questions, corrections, or the underlying data, please get in touch.
